similarity to OPV1. The differences in nucleotide sequences among the outbreak isolates suggest that the virus has been circulating for approximately 2 years in an area where vaccination coverage is very low and that the virus had accumulated genetic changes that restored the essential properties of wild poliovirus.

The ministries of health of the Dominican Republic and Haiti, with the assistance of the Pan American Health Organization and CDC, are investigating the outbreak to determine the extent of spread, evaluate the reasons for the outbreak, and initiate appropriate control measures. The Dominican Republic has started a nationwide mass vaccination campaign with OPV, and three nationwide vaccination rounds with OPV are planned for January, February, and March 2001 in Haiti.

Circulation of OPV-derived polioviruses in areas with very low OPV coverage has been documented in one other setting – type 2 OPV-derived virus circulated in Egypt for an estimated 10 years (1983-1993) and was associated with >30 reported cases2. Vaccination coverage was very low in the affected areas, and circulation of a vaccine-derived poliovirus stopped when OPV coverage increased. The key factor in controlling circulating OPV-derived viruses and wild polioviruses is achieving and maintaining high vaccination coverage. No evidence for circulation of OPV-derived virus has been found in areas with high coverage.

Since 1991, no cases of polio attributed to wild poliovirus have been detected in the Western Hemisphere. The current outbreak underscores the need for polio-free areas to maintain high coverage with polio vaccine until global polio eradication has been achieved. OPV is safe and effective and recommended for the eradication of polio. All countries should maintain high quality AFP and poliovirus surveillance and accelerate current activities to complete the global eradication of wild polioviruses.

Health care providers should consider polio as a diagnosis in case-patients with a history of travel to other countries of the Western Hemisphere from the Dominican Republic and Haiti who present with AFP usually accompanied by fever. These possible cases should be investigated properly, including collection of stool samples. Suspected cases should be reported immediately to state and local health departments.

Travelers to the Dominican Republic and Haiti who are not vaccinated adequately should be considered at risk for polio. All travelers should be vaccinated fully against polio according to national vaccination policies3.

Polio Technical Document

In their continuing support of the global campaign to eradicate polio, the United States Pharmacopeia (USP) has updated the technical document entitled "Poliomyelitis, OPV and Misconceptions on Vaccinations." It includes a discussion of the disease* and its prevention with oral poliovirus vaccine. The report addresses misinformation and superstitions known to exist in different parts of the world that may prevent people from fully immunizing their families.

Continued on page 12
The document was reviewed by international polio experts, including the USP Expert Advisory Panels on Infectious Disease Therapy, International Health, and Pediatrics; the World Health Organization (WHO); the United Nations Children’s Fund (UNICEF); the US Centers for Disease Control and Prevention (CDC); and others from the general public.

“Poliomyelitis, OPV and Misconceptions on Vaccinations” is available in English, French, and Russian in print (limited quantities) and on the USP web page (www.usp.org) under “Drug Information” in downloadable PDF files.

Contact Marilyn Foster at 301-816-8593 or via email at mlf@usp.org to request copies. Please indicate which language(s) you would like to receive and how many copies.

*The discussion of acute poliomyelitis from the earlier document was reprinted in the Fall of 1998 in Polio Network News (Volume 15, Number 4).

**Polio Eradicated in Western Pacific**

The World Health Organization (WHO) has announced that the poliovirus has not been found in the Western Pacific for three years. The last known case of indigenous poliovirus transmission occurred in Cambodia in March 1997. The region comprises 37 countries from China to French Polynesia with an estimated population of 1.6 billion persons (27% of the world’s population).
